ONE THING

TECHNICAL DOCUMENTATION | BUYER REVIEW

1. Product architecture

One Thing is a native Android application. The available project information identifies Kotlin as the implementation language, XML for layouts and local SharedPreferences/JSON storage. The documented core product does not require a remote backend or external API.

2. Project identifiers and Android configuration

Property	Recorded configuration
Application/package ID	com.pratik.onething
Application type	Android application
Implementation language	Kotlin
UI technology	XML layouts
Local persistence	SharedPreferences / JSON
Minimum SDK	24 (Android 7.0)
Target SDK	34
Version	1.0 (versionCode 1)

3. Functional modules

Task setup: accepts a user-defined task and focus duration. Supported duration range is 1–90 minutes, with 15, 25, 45 and 90-minute presets.

Focus session: displays a live countdown and progress, supports background sessions and uses a completion notification/alarm.

Distraction tracking: records slips/distractions associated with focus sessions.

History and progress: retains the last 30 sessions and presents a weekly summary and daily streak information.

Motivational content: displays motivational quotes.

4. Build and release

The project was built on-device using CodeAssist. CodeAssist's native project configuration uses **module.toml** and its own build/signing interface; do not assume a conventional Gradle wrapper or a standard Android Studio Gradle project is included. Confirm the exact build instructions against the source archive supplied to the buyer.

The release build was configured in CodeAssist to use the **OneThingFinal** signing keystore. The uploaded release APK was checked and its signing certificate fingerprint matched the new keystore shown in CodeAssist. The signing keystore and credentials are sensitive handover assets and must not be placed in a public repository.

5. Storage, network and privacy considerations

The documented app data is stored locally using SharedPreferences/JSON. No cloud account, backend service or external API is required for the core functionality described here. A buyer should inspect the manifest, permissions, source code and actual network behavior before making privacy or security representations to users.

6. Known review items

The prior development review flagged areas requiring additional verification: session finalization and foreground-service lifecycle around the alarm/receiver flow; possible duplicate slip counting when pause and explicit exit paths both run; notification-channel behavior; and the absence of an automated test suite. These are review findings, not a claim that every current build reproduces each issue.

Before commercial release, the buyer should test fresh install, session completion, early exit, background/foreground transitions, notification behavior, persistence after process death, Android-version compatibility and upgrade behavior.

7. Buyer handover checklist

- Complete source project archive and all required assets
- Build instructions and dependency/version notes
- Release APK and package/version details
- Keystore file and alias/password, transferred securely after closing
- Inventory of third-party libraries and applicable licenses
- List of known issues and test results
- Written IP assignment and asset-transfer record

8. Scope and accuracy

This document summarizes currently recorded project details. It is not a substitute for a source-code audit, penetration test, privacy assessment or independent QA report. Any feature, dependency, permission or build step not explicitly documented here must be verified from the delivered project.
